

# Building Real-Time Applications

**Yulia Tenincheva**

Senior Cloud Engineer, MentorMate

# Today's Agenda

- Buffers
- Streams
- WebSockets

---

# Buffers

---

# What is a Buffer?

- Any data read (written) to (from) a file (network) is read (written) in **Bytes**.
- Buffer objects are used to represent a fixed-length sequence of bytes. To work with binary data, we need access to these buffers.

```
<Buffer ff f3 44 c4 00 11 88 96 20 00 ca 52 4c 03 e0 6d  
c6 4c 53 75 7b e4 b0 f4 22 1f 99 04 7a 33 86 43 6a 3e  
94 64 13 44 61 7a 6d 36 85 05 cb 19 27 83 07 de ...  
4270 more bytes>
```

# Encoding Demo

```
var fs = require('fs');  
fs.readFile('./names.txt', function (er, buf) {  
  console.log(buf.toString());  
});
```

toString by default will  
convert data into a  
UTF-8 encoded string.

## Buffers - Foreign Language Encoding Ascii and UTF-8

```
> b=Buffer.from('abcde','ascii')  
<Buffer 61 62 63 64 65>  
> b=Buffer.from('abcde')  
<Buffer 61 62 63 64 65>  
> b=Buffer.from('abcdé','ascii')  
<Buffer 61 62 63 64 e9>  
> b=Buffer.from('abcdé')  
<Buffer 61 62 63 64 c3 a9>
```

ASCII

UTF-8

This character is unknown and is encoded as a question mark - hex e9

UTF-8 requires 2 bytes to encode the french é

Supported by Node.js:

- Character:

utf8

utf16le

latin1

ascii

- Binary-to-text:

base64

hex

| ASCII   | VERSUS | UNICODE  |
|---|--------|--|
| ASCII   |        | UNICODE  |
| A character encoding standard for electronic communication    |        | A computing industry standard for consistent encoding, representation, and handling of text expressed in most of the world's writing systems |
| Stands for American Standard Code for Information Interchange |        | Stands for Universal Character Set   |
| Supports 128 characters                                       |        | Supports a wide range of characters  |
| Uses 7 bits to represent a character                          |        | Uses 8bit, 16bit or 32bit depending on the encoding type   |
| Requires less space   |        | Requires more space  |

# Streams

---

# Buffers vs Streams

Using streamable APIs means I/O operations potentially use less memory.

---

**Streams** make programming  
in node **simple, elegant** and  
**composable.**

---

—James Hillday

# Why Streams?

- Allows for data processing chunk-by-chunk or line-by-line
- Memory efficient - do not need to save entire large file/buffer to memory
- Allows for more functional approach - small modules can be chained
- Streams are essential for scalability

# How streams work?

- Streams are Event Emitters
- Streams are the basic I/O of node processes
- Writable streams must send a signal back to the readable streams that they are ready for more data.

```
// readable process.stdin is directly echoed back to process.stdout  
process.stdin.pipe(process.stdout);
```

# Bestiary of Streams

- Readable - can act like the source, but not the destination
- Writable - can act as the destination, but can not be a source
- Duplex - both Readable and Writable
- Transform - between Readable and Writable

## Readable Streams

HTTP responses, on the client

HTTP requests, on the server

fs read streams

zlib streams

crypto streams

TCP sockets

child process stdout and stderr

process.stdin

## Writable Streams

HTTP requests, on the client

HTTP responses, on the server

fs write streams

zlib streams

crypto streams

TCP sockets

child process stdin

process.stdout, process.stderr

# Bestiary of Streams

- Readable - can act like the source, but not the destination
- Writable - can act as the destination, but can not be a source
- Duplex - both Readable and Writable
- Transform - between Readable and Writable

## Readable Streams

### Events

- data
- end
- error
- close
- readable

### Functions

- pipe(), unpipe()
- read(), unshift(), resume()
- pause(), isPaused()
- setEncoding()

## Writable Streams

### Events

- drain
- finish
- error
- close
- pipe/unpipe

### Functions

- write()
- end()
- cork(), uncork()
- setDefaultEncoding()

# Resources & Demos

- Node's most powerful and misunderstood feature - Streams ([chapter](#) from a book)
- Everything you should know about streams
  - [blog post](#)
- Demos:
  - Buffer vs Streams - `fs.readFile` vs `fs.createReadStream`
  - Pipe example, pipe to server response
  - Encrypt/Decrypt Transform stream example

# Readable Streams

- All readable streams start in the **paused mode by default**. One of the ways of switching the mode of a stream to flowing is to attach a 'data' event listener.
- A way to switch the readable stream to a flowing mode manually is to call the **stream.resume** method. If there are no handlers, the data is **lost**.

**Demo:** Write a custom Readable stream

```
const fs = require('fs');
const stream = fs.createReadStream('./small.txt');

stream.resume();

setTimeout(() => {
  stream.on('data', (data) => { console.log(data); });
}, 2000);
```

Paused

stream.read()

stream.resume()

Flowing

EventEmitter

stream.pause()

---

# WebSockets

---

# WebSockets

- WebSockets is a **bidirectional** communication **protocol** over the web
- **Reduces latency**, saves bandwidth and CPU power
- Provides **enhanced capabilities** to HTML5 applications

# How WebSockets work?

- Establish connection, open handshake  
WebSocket URIs use a new scheme **ws:**  
(or **wss:** for a secure WebSocket)

```
"ws:" "//" host [ ":" port ] path [ "?" query ]  
"wss:" "//" host [ ":" port ] path [ "?" query ]
```

- WebSocket connections are established by **upgrading** an HTTP request
- WebSocket is a *framed* protocol, meaning that a chunk of data (a message) is divided into a number of discrete chunks, with the size of the chunk encoded in the frame.

# Socket.IO

- **Socket.IO** provides **additional features** over a plain WebSocket object. It is NOT a WebSocket implementation!
- Socket.io NPM [Package](#)
- Emit [cheatsheet](#)
- Client [installation](#)
